					The paper establishes that while modern remote programming labs and automated graders can process vast numbers of student submissions, they typically rely on final outputs or logs without a way to verify if an ordered execution trace has been tampered with or corrupted after trusted collection. It introduces TraceLock-EDU as a sequence-evidence layer.	The premise correctly identifies a gap regarding ordered execution traces. To make the introduction even stronger, the paper (or future work building on it) could emphasize *why* standard file-level or database checksums fall short in educational contexts—specifically, how relational databases or log files can suffer from partial writes or silent row reordering that basic hashes fail to contextualize without an order-sensitive algebraic accumulator.
